

Third Exam
Monday, May 20

Simpler polymorphism demo

(~mikeec/cs32/demos/figures)

- Base: Figure has `virtual void print()`
 - `print()` is used in `printAt(lines)`
- Derived: Rectangle *just* overrides `print()`
- Which `print()` is used in the following code?

```
Figure *ptr = new Rectangle,  
        &ref = *new Rectangle('Q', 5, 10, 4);  
ptr->printAt(1); ref.printAt(1);
```
- What if `print()` was not declared `virtual`?
- What if line 2 above just had `ref`, not `&ref`?
 - To know why, see “slicing” ... a few slides from now

“Pure virtual” and abstract classes

- Actually class Figure’s print() function is useless
 - It should have been a **pure virtual function**:
`virtual void draw() const = 0;`
 - Says not defined in this class – means any derived class must define its own version, or be abstract itself
- A class with one or more pure virtual functions is an **abstract class** – so *it can only be a base class*
 - An actual instance would be an incomplete object
 - So *any instance must be a derived class instance*

Types when inheritance is involved

- Consider: `void func (Sale &x) {...}` or
similarly: `void func (Sale *xp) {...}`
 - What type of object is `x` (or `*xp`), really? Is it a `Sale`?
 - Or is it a `DiscountSale`, or even a `CrazyDiscountSale`?
- Just `Sale` members are available
 - But might be virtual, and `Sale` might even be abstract
 - `&` and `*` variables allow polymorphism to occur
- Contrast: `void func (Sale y) {...}`
 - What type of object is `y`? It's a `Sale`. Period.
 - Derived parts are “sliced” off by `Sale`'s copy ctor
 - Also in this case, `Sale` cannot be an abstract class

Type compatibility example

```
class Pet {
public: // pls excuse bad info hiding
    string name;
    virtual void print();
};

class Dog : public Pet {
public:
    string breed;
    virtual void print();
};
```

- Consider:
Dog d; Pet p;
d.name = "Tiny";
d.breed = "Mutt";
p = d; // "slicing" here
– All okay – a Dog "is a" Pet
- Reverse is not okay
– A Pet might be a Bird, or ...
- And p.breed? Nonsense!
- Also see [slicing.cpp](#) at
~mikec/cs32/demos/

Destructors should be virtual

- Especially if class has virtual functions
- Derived classes might allocate resources via a base class reference or pointer:

```
Base *ptrBase = new Derived;  
... // a redefined function allocates resources  
delete ptrBase;
```

- If dtor not virtual, derived dtor is not run!
- If dtor is virtual – okay: run derived dtor, immediately followed by base dtor

Casting and inherited types

- Consider again: `Dog d; Pet p;`
- “Upcasting” (descendent to ancestor) is legal:
 - `p = d; // implicitly casting “up”`
 - `p = static_cast<Pet>(d); // like (Pet)d`
 - But objects sliced if not pointer or reference
- Other way (“downcasting”) is a different story:
 - `d = static_cast<Dog>(p); // ILLEGAL`
 - Can only do by pointer and *dynamic cast* :
`Pet *pptr = new Dog; // we know it's a Dog`
`Dog *dptr = dynamic_cast<Dog*>(pptr)`
 - But can be dangerous, and is rarely done

Multiple inheritance and virtual

- Idea: a `ClockRadio` is a `Radio` *and* an `AlarmClock`
 - But what if class `Radio` and class `AlarmClock` are both derived from another class, say `Appliance`?
 - Doesn't each derived object contain an `Appliance` portion?
 - So wouldn't a `Clockradio` have two copies of that portion, and how can such a scheme possibly work properly?
- Answer: it can work, but only by using *virtual* inheritance!

```
class Radio : virtual public Appliance;
class AlarmClock : virtual public Appliance;
class ClockRadio : public Radio, public AlarmClock;
```

 - Now a `Clockradio` has just one `Appliance` portion, not two
- See demo code in `~mikec/cs32/demos/multi-inherit`
- But note: hierarchy is still messed up, and still lots of chances for ambiguity – best to avoid multi-inheritance!

How do virtual functions work?

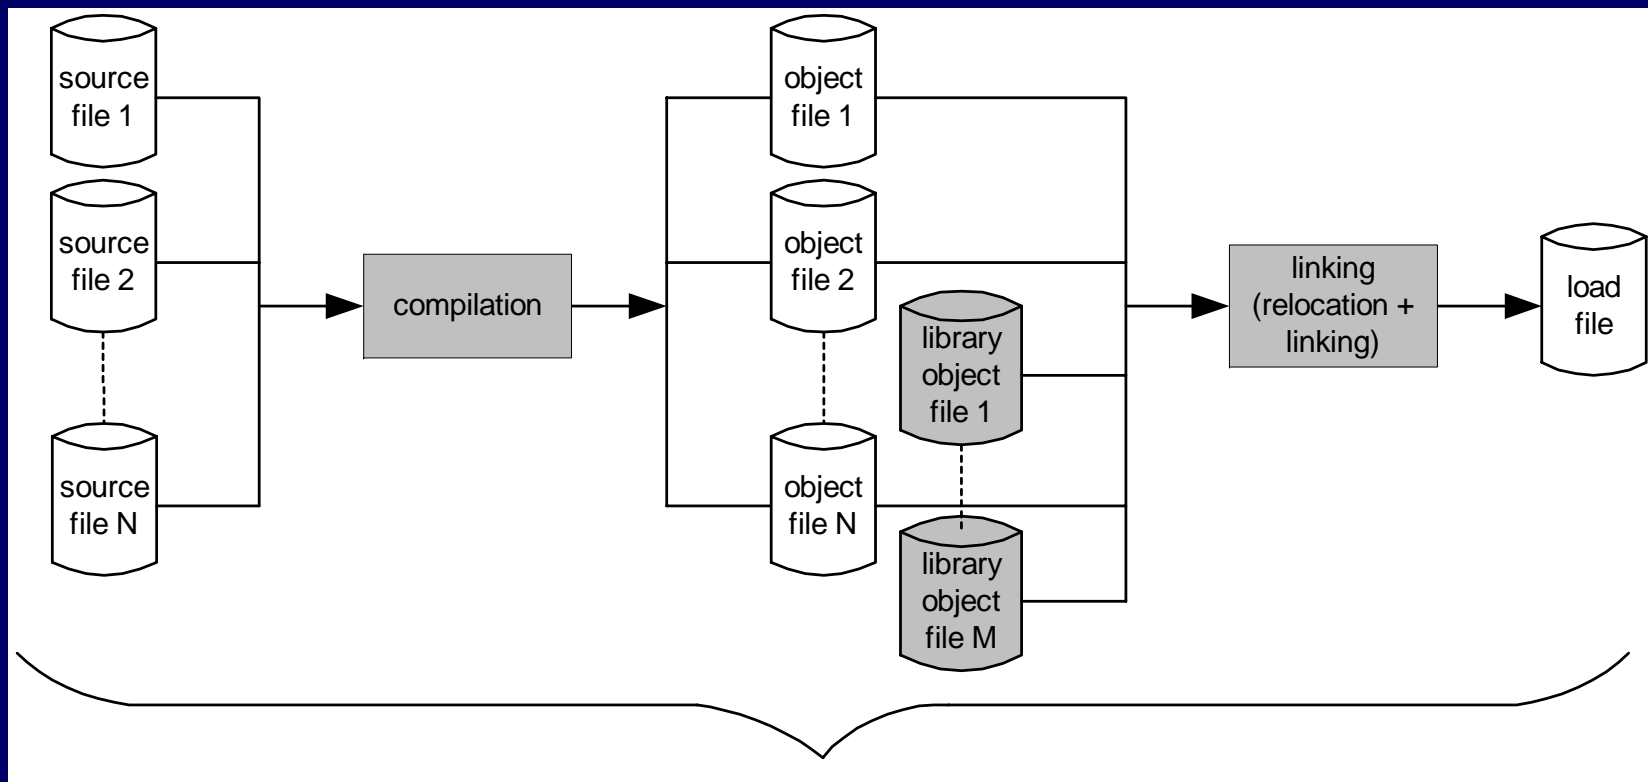

- Not exactly magic, but safe to consider it so
- `virtual` tells compiler to “wait for instructions” until the function is used in a program
- So the compiler creates a **virtual function table** for the class, with pointers to all virtual functions
- In turn, every *object* of such a class will be made to store a pointer to its own class’s virtual function table – try `.../demos/sizeofvirtual.cpp`
- At runtime: follow the pointers to find the code!

Memory and C/C++ modules

From Reading #6

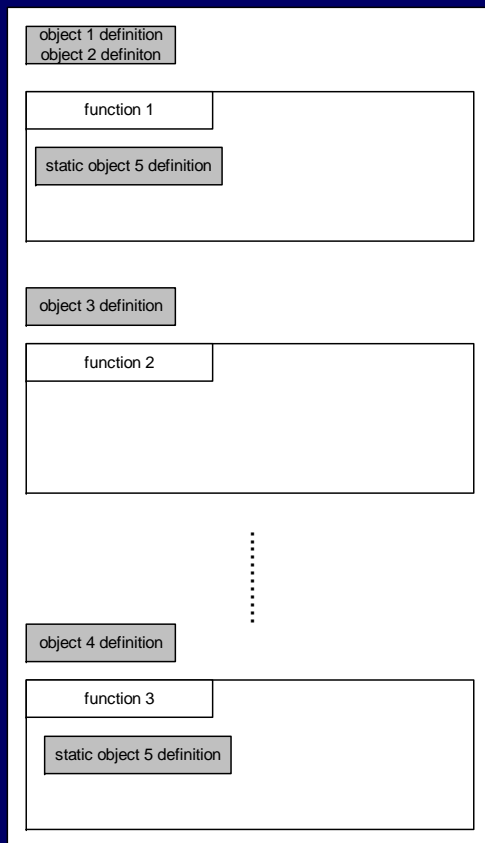

Will return to OOP topics
(templates and library tools) soon

Compilation/linking revisited

Usually performed by gcc/g++ in one uninterrupted sequence

Layout of C/C++ programs

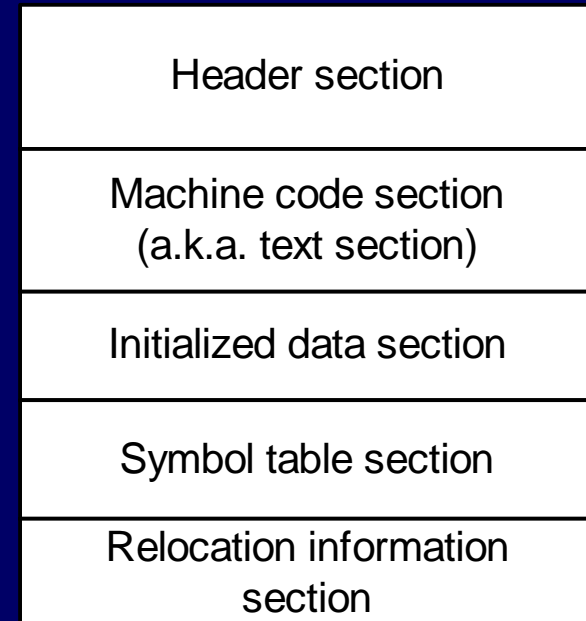

Source code

... becomes

Object
module →

A sample C program – demo.c

```
#include <stdio.h>

int a[10]={0,1,2,3,4,5,6,7,8,9};
int b[10];

void main(){
    int i;
    static int k = 3;

    for(i = 0; i < 10; i++) {
        printf("%d\n",a[i]);
        b[i] = k*a[i];
    }
}
```

- Has text section of course: the machine code
- Has initialized global data: a
- Uninitialized global data: b
- Static data: k
- Has a local variable: i

A possible structure of demo.o

Offset	Contents	Comment
Header section		
0	124	number of bytes of Machine code section
4	44	number of bytes of initialized data section
8	40	number of bytes of Uninitialized data section (array <code>b[]</code>) (not part of this object module)
12	60	number of bytes of Symbol table section
16	44	number of bytes of Relocation information section
Machine code section (124 bytes)		
20	X	code for the top of the <code>for</code> loop (36 bytes)
56	X	code for call to <code>printf()</code> (22 bytes)
68	X	code for the assignment statement (10 bytes)
88	X	code for the bottom of the <code>for</code> loop (4 bytes)
92	X	code for exiting <code>main()</code> (52 bytes)
Initialized data section (44 bytes)		
144	0	beginning of array <code>a[]</code>
148	1	
:		
176	8	
180	9	end of array <code>a[]</code> (40 bytes)
184	3	variable <code>k</code> (4 bytes)
Symbol table section (60 bytes)		
188	X	array <code>a[]</code> : offset 0 in Initialized data section (12 bytes)
200	X	variable <code>k</code> : offset 40 in Initialized data section (10 bytes)
210	X	array <code>b[]</code> : offset 0 in Uninitialized data section (12 bytes)
222	X	<code>main</code> : offset 0 in Machine code section (12 bytes)
234	X	<code>printf</code> : external, used at offset 56 of Machine code section (14 bytes)
Relocation information section (44 bytes)		
248	X	relocation information

Object module contains neither uninitialized data (`b`), nor any local variables (`i`)
