## Closest Pair Problem

- Given $n$ points in $d$-dimensions, find two whose mutual distance is smallest.
- Fundamental problem in many applications as well as a key step in many algorithms.

- A naive algorithm takes $O\left(d n^{2}\right)$ time.
- Element uniqueness reduces to Closest Pair, so $\Omega(n \log n)$ lower bound.
- We will develop a divide-and-conquer based $O(n \log n)$ algorithm; dimension $d$ assumed constant.

## 1-Dimension Problem

- 1D problem can be solved in $O(n \log n)$ via sorting.
- Sorting, however, does not generalize to higher dimensions. So, let's develop a divide-and-conquer for 1D.
- Divide the points $S$ into two sets $S_{1}, S_{2}$ by some $x$-coordinate so that $p<q$ for all $p \in S_{1}$ and $q \in S_{2}$.
- Recursively compute closest pair $\left(p_{1}, p_{2}\right)$ in $S_{1}$ and $\left(q_{1}, q_{2}\right)$ in $S_{2}$.

median $m$
- Let $\delta$ be the smallest separation found so far:

$$
\delta=\min \left(\left|p_{2}-p_{1}\right|,\left|q_{2}-q_{1}\right|\right)
$$

## 1D Divide \& Conquer

median $m$

- The closest pair is $\left\{p_{1}, p_{2}\right\}$, or $\left\{q_{1}, q_{2}\right\}$, or some $\left\{p_{3}, q_{3}\right\}$ where $p_{3} \in S_{1}$ and $q_{3} \in S_{2}$.
- Key Observation: If $m$ is the dividing coordinate, then $p_{3}, q_{3}$ must be within $\delta$ of m.
- In 1D, $p_{3}$ must be the rightmost point of $S_{1}$ and $q_{3}$ the leftmost point of $S_{2}$, but these notions do not generalize to higher dimensions.
- How many points of $S_{1}$ can lie in the interval $(m-\delta, m]$ ?
- By definition of $\delta$, at most one. Same holds for $S_{2}$.

## 1D Divide \& Conquer

median m

- Closest-Pair ( $S$ ).
- If $|S|=1$, output $\delta=\infty$.

If $|S|=2$, output $\delta=\left|p_{2}-p_{1}\right|$.
Otherwise, do the following steps:

1. Let $m=\operatorname{median}(S)$.
2. Divide $S$ into $S_{1}, S_{2}$ at $m$.
3. $\delta_{1}=$ Closest-Pair $\left(S_{1}\right)$.
4. $\delta_{2}=$ Closest-Pair $\left(S_{2}\right)$.
5. $\delta_{12}$ is minimum distance across the cut.
6. Return $\delta=\min \left(\delta_{1}, \delta_{2}, \delta_{12}\right)$.

- Recurrence is $T(n)=2 T(n / 2)+O(n)$, which solves to $T(n)=O(n \log n)$.

## 2-D Closest Pair

- We partition $S$ into $S_{1}, S_{2}$ by vertical line $\ell$ defined by median $x$-coordinate in $S$.
- Recursively compute closest pair distances $\delta_{1}$ and $\delta_{2}$. Set $\delta=\min \left(\delta_{1}, \delta_{2}\right)$.
- Now compute the closest pair with one point each in $S_{1}$ and $S_{2}$.

- In each candidate pair $(p, q)$, where $p \in S_{1}$ and $q \in S_{2}$, the points $p, q$ must both lie within $\delta$ of $\ell$.

## 2-D Closest Pair

- At this point, complications arise, which weren't present in 1D. It's entirely possible that all $n / 2$ points of $S_{1}$ (and $S_{2}$ ) lie within $\delta$ of $\ell$.

- Naively, this would require $n^{2} / 4$ calculations.
- We show that points in $P_{1}, P_{2}$ ( $\delta$ strip around $\ell$ ) have a special structure, and solve the conquer step faster.

## Conquer Step

- Consider a point $p \in S_{1}$. All points of $S_{2}$ within distance $\delta$ of $p$ must lie in a $\delta \times 2 \delta$ rectangle $R$.

- How many points can be inside $R$ if each pair is at least $\delta$ apart?
- In 2D, this number is at most 6!
- So, we only need to perform $6 \times n / 2$ distance comparisons!
- We don't have an $O(n \log n)$ time algorithm yet. Why?

## Conquer Step Pairs

- In order to determine at most 6 potential mates of $p$, project $p$ and all points of $P_{2}$ onto line $\ell$.

- Pick out points whose projection is within $\delta$ of $p$; at most six.
- We can do this for all $p$, by walking sorted lists of $P_{1}$ and $P_{2}$, in total $O(n)$ time.
- The sorted lists for $P_{1}, P_{2}$ can be obtained from pre-sorting of $S_{1}, S_{2}$.
- Final recurrence is $T(n)=2 T(n / 2)+O(n)$, which solves to $T(n)=O(n \log n)$.

## $d$-Dimensional Closest Pair

- Two key features of the divide and conquer strategy are these:

1. The step where subproblems are combined takes place in one lower dimension.
2. The subproblems in the combine step satisfy a sparsity condition.
3. Sparsity Condition: Any cube with side length $2 \delta$ contains $O(1)$ points of $S$.
4. Note that the original problem does not necessarily have this condition.

## The Sparse Problem

- Given $n$ points with $\delta$-sparsity condition, find all pairs within distance $\leq \delta$.
- Divide the set into $S_{1}, S_{2}$ by a median place $H$. Recursively solve the problem in two halves.
- Project all points lying within $\delta$ thick slab around $H$ onto $H$. Call this set $S^{\prime}$.
- $S^{\prime}$ inherits the $\delta$-sparsity condition. Why?.
- Recursively solve the problem for $S^{\prime}$ in $d-1$ space.
- The algorithms satisfies the recurrence

$$
U(n, d)=2 U(n / 2, d)+U(n, d-1)+O(n)
$$

which solves to $U(n, d)=O\left(n(\log n)^{d-1}\right)$.

## Getting Sparsity

- Recall that divide and conquer algorithm solves the left and right half problems recursively.
- The sparsity holds for the merge problem, which concerns points within $\delta$ thick slab around $H$.

- If $S$ is a set where inter-point distance is at least $\delta$, then the $\delta$-cube centered at $p$ contains at most a constant number of points of $S$, depending on $d$.

## Proof of Sparsity

- Let $C$ be the $\delta$-cube centered at $p$. Let $L$ be the set of points in $C$.
- Imagine placing a ball of radius $\delta / 2$ around each point of $L$.
- No two balls can intersect. Why?
- The volume of cube $C$ is $(2 \delta)^{d}$.
- The volume of each ball is $\frac{1}{c_{d}}(\delta / 2)^{d}$, for a constant $c_{d}$.
- Thus, the maximum number of balls, or points, is at most $c_{d} 4^{d}$, which is $O(1)$.

## Closest Pair Algorithm

- Divide the input $S$ into $S_{1}, S_{2}$ by the median hyperplane normal to some axis.
- Recursively compute $\delta_{1}, \delta_{2}$ for $S_{1}, S_{2}$. Set $\delta=\min \left(\delta_{1}, \delta_{2}\right)$.
- Let $S^{\prime}$ be the set of points that are within $\delta$ of $H$, projected onto $H$.
- Use the $\delta$-sparsity condition to recursively examine all pairs in $S^{\prime}$-there are only $O(n)$ pairs.
- The recurrence for the final algorithm is:

$$
\begin{aligned}
T(n, d) & =2 T(n / 2, d)+U(n, d-1)+O(n) \\
& =2 T(n / 2, d)+O\left(n(\log n)^{d-2}\right)+O(n) \\
& =O\left(n(\log n)^{d-1}\right)
\end{aligned}
$$

## Improving the Algorithm

- If we could show that the problem size in the conquer step is $m \leq n /(\log n)^{d-2}$, then $U(m, d-1)=O\left(m(\log m)^{d-2}\right)=O(n)$.
- This would give final recurrence $T(n, d)=2 T(n / 2, d)+O(n)+O(n)$, which solves to $O(n \log n)$.
- Theorem: Given a set $S$ with $\delta$-sparsity, there exists a hyperplane $H$ normal to some axis such that

1. $\left|S_{1}\right|,\left|S_{2}\right| \geq n / 4 d$.
2. Number of points within $\delta$ of $H$ is
$O\left(\frac{n}{(\log n)^{d-2}}\right)$.
3. $H$ can be found in $O(n)$ time.

## Sparse Hyperplane

- We prove the theorem for 2D. Show there is a line with $\alpha \sqrt{n}$ points within $\delta$ of it, for some constant $\alpha$.
- For contradiction, assume no such line exists.
- Partition the plane by placing vertical lines at distance $2 \delta$ from each other, where $n / 8$ points to the left of leftmost line, and right of rightmost line.

## Sparse Hyperplane

- If there are $k$ slabs, we have $k \alpha \sqrt{n} \leq 3 n / 4$, which gives $k \leq \frac{3}{4 \alpha} \sqrt{n}$.

- Similarly, if there is no horizontal line with desired properties, we get $l \leq \frac{3}{4 \alpha} \sqrt{n}$.
- By sparsity, number of points in any $2 \delta$ cell is some constant $c$.

## Sparse Hyperplane

- This gives that the num. of points inside all the slabs is at most $c k l$, which is at most $\left(\frac{3}{4 \alpha}\right)^{2}$ cn.
- Since there are $\geq n / 2$ points inside the slabs, this is a contradiction if we choose $\alpha \geq \frac{\sqrt{18 c}}{4}$.
- So, one of these $k$ vertical of $l$ horizontal lines must satisfy the desired properties.
- Since we know $\delta$, we can check these $k+l$ lines and choose the correct one in $O(n)$ time.

## Optimal Algorithm

- Actually we can start the algorithm with such a hyperplane.
- The divide and conquer algorithm now satisfies the recurrence $T(n, d)=2 T(n / 2, d)+U(m, d-1)+O(n)$.
- By new sparsity claim, $m \leq n /(\log n)^{d-2}$, and so $U(m, d-1)=O\left(m(\log m)^{d-2}\right)=O(n)$.
- Thus, $T(n, d)=2 T(n / 2, d)+O(n)+O(n)$, which solves to $O(n \log n)$.
- Solves the Closest Pair problem in fixed $d$ in optimal $O(n \log n)$ time.
